AIM

The main aim of this project is to allow people to communicate manipulating time and space; in this way busy people or that live in different cities can keep in contact.

A system of little boxes, set in different places, connect each other and send daily messages that users can listen and record whenever they like. The messages can be vocals but they can also be sounds or noises.

USERS

The users will be people that love to keep in touch with family and friends in a regular basic; they can live near each other, but also at hundred miles of distance.

They don't like the cold communication offered by a computer screen or a telephone; for this reason we're concentrating on sounds research so to give each one an individual personality.

CONTEXT OF USE

We're imagining our little box over a table, inside a nice and intimate room, while the user move in that place with confidence and habit. It surely know the person at the other end and can imaging him/her in their personal space. Other way the boxes can also be move by the users in order to record sounds that are playing outside.

MOOD

We would love for our users to feel at ease using this product, thanks to the simple and intuitive interaction. The physical aspects and behaviour of the object will produce an intimate and poetic atmosphere, while the mood is a lot related to the messages that are exchanged.

THE TUULI FAMILY

The Tuuli family is made of three boxes that outside are made of the same white plastic, but the inside reveal their real strong personality with different vivid colours.

Also, if from one side they have similar input and output, in the other side they show a personal character by interacting with the users with different behaviours.

PLAY THE MESSAGE:

WHY ARDUINO IS NOT THE BEST

After some experiment we noticed that it was really difficult to generate a good quality sound with arduino, because of the conversion of the sound

- from analogue to digital (using the microphone)
- and from digital to analogue (using speakers).

The result was a noise and disturbed sound, really unpleasant.

PLAY THE MESSAGE:

OUR SOLUTION

“Wave Shield” is an analog audio shield for the Arduino and it allows to play audio sound bytes.

WHAT'S ABOUT RECORDING?

The voice shield can give and receive sounds, but there can be also the possibility to implement it with a microphone. In this way the microphone can use the sound converter of the shield and record the voice (analog) with good quality.

SOUND IN PROTOTYPING

For the prototype we didn't use the wave shield, because of the difficulty to write the right code. Instead we connected the two elements, the microphone and the speaker, to a computer and we are going to control them with a processing code.
